1 Set Theory

1.1 Introduction

Quick recap on Naive set theory, meaning:

- 1. Introducing the basic concept of sets;
- 2. Introduce notation;
- 3. Illustrate Union, Intersection, and Set Difference operations;
- 4. Venn diagrams as proof;
- 5. Power sets;
- 6. How to proof with more rigor.

1.2 Set Definition

Question: Why are sets relevant to computing?

We have to represent data to compute it. To group data, we put it into sets. Some sets that I have seen before:

The set of natural numbers: $\mathbb{N} = \{1, 2, 3, ...\}$ The set of integers: $\mathbb{Z} = \{..., -3, -2, -1, 0, 1, 2, 3, ...\}$ Question: What are sets?

A set is a collection of objects, called elements of the set. The elements of a set can be anything, but they must be distinct.

1.3 Notation

Sets are denoted with capital letters, e.g. A, B, C. The elements of a set are listed inside curly brackets:

$$A = \{1, 2, 3\}$$

$$B = \{a, b, c, d, e, f, g, h\}$$

1.3.1 Cardinality

The cardinality of a set is the number of elements in the set. The cardinality of a set is denoted with vertical bars, with the hash, or alternatively, the function card:

$$\begin{aligned} \operatorname{Card}(A) &= |A| = 3 \\ \#\{1,2,3,4,5\} &= 5 \\ \#A &= 3 \\ \#\mathbb{N} &= \infty \end{aligned}$$

1.3.2 Abstraction axiom

GIven a property P(x), we can define a set A as:

$$A = \{x | P(x)\}$$

In other words, whatever property P, there exists a set A containing the objects that satisfy P and only these objects.

1.3.3 Set builder notation

Other than enumerating the elements of a set, there are other ways to describe a set. Verbal descriptions and adding an inclusion rule to the set builder notation are two more examples:

$$C = \{x | x \in \mathbb{N}, 0 \le x \le 5\}$$

= $\{x | x \text{ is in the appropriate set}, 0 \le x \le 5\}$

1.3.4 Empty set

The empty set is a set with no elements. It is denoted \emptyset or $\{\}$.

$$\emptyset = \{\}$$
$$\emptyset \neq \{\emptyset\}$$

1.4 Basic set operations

1.4.1 Membership

The membership relation is denoted \in and is used to indicate that an element is in a set. Conversely, \notin is used to indicate that an element is not in a set.

Let the set
$$A = \{1, 2, 3\}$$

 $1 \in A = \text{True}$
 $3 \notin A = \text{False}$

To denote a subset, we use \subseteq . Since a subset can include the set itself, we use \subset to denote a proper subset.

Let the set
$$A = \{1, 2, 3\}$$

 $\{1, 2\} \subseteq A = \text{True}$
 $\{1, 2, 3\} \subset A = \text{False}$

1.4.2 Union, intersection, and set difference

The union of two sets A and B is denoted $A \cup B$ and contains all elements of both sets.

The intersection $A \cap B$ contains elements common to both.

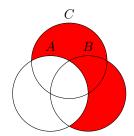

Set diffrence $A \setminus B$ contains elements in A but not in B. (Note: A must come first, otherwise the result is different.)

$$A \cup B = \{1, 2, 3, a, b, c\}$$
$$A \cap B = \{1, 2, 3\}$$
$$A \setminus B = \{1, 2, 3\}$$

1.5 Venn diagrams

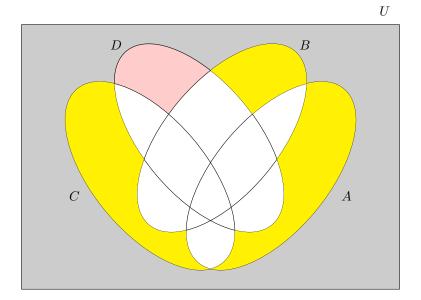

Venn diagrams are a way to visualise sets and their operations. Use circles to represent sets, and shading to distinguish areas of interest.

Let the set = $\{1, 2, 3\}$ Let the set = $\{2, 3, 4\}$ Let the set = $\{3, 4, 5\}$ $(C \cup B) \cap A = \{4, 5\}$

Here is a more complicated example involving 4 sets:

 $Refrenced\ from\ \texttt{https://www.overleaf.com/latex/examples/example-venn-diagram-with-isolated-xjptmqsjfdlc}$

This covers the basics of set notation and operations.

1.6 Power sets

The power set of a set is the set of all subsets of that set.

The power set of a set A is denoted in various ways, including 2^A , $\mathcal{P}(A)$, $\mathbb{P}(A)$, or $\wp(A)$.

Let the set
$$A = \{1, 2, 3\}$$

$$\wp(A) = \{\emptyset, \{1\}, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1, 2, 3\}\}$$
 More generally: $\mathbb{P}(A) = \{B | B \subseteq A\}$

1.7 Proofs

1.7.1 Proof by property

Proposition (example from lecutre notes): For any sets A, B, and C:

$$A \setminus (B \cup C) = (A \setminus B) \cap (A \setminus C)$$

Recapping some of the basic properties of sets, using sets S and T, and element x:

| Property 1: | $S \subseteq T \text{ and } T \subseteq S \iff S = T$ |
|-------------|---|
| Property 2: | (For any $x \in S \implies x \in T$) $\iff S \subseteq T$ |
| Property 3: | $x \in S$ and $x \in T \iff x \in S \cap T$ |
| Property 4: | $x \in S \text{ or } x \in T \iff x \in S \cup T$ |
| Property 5: | $x \in S \text{ and } x \notin T \iff x \in S \setminus T$ |
| Property 6: | $x \notin S \text{ and } x \notin T \iff x \notin T \cup S$ |

Using property 1, we can prove that two sets are equal by proving that each is a subset of the other.

Let
$$x \in A \setminus (B \cup C)$$

 $\iff x \in A \text{ and } x \notin B \cup C$
 $\iff x \in A \text{ and } x \notin B \text{ and } x \notin C$
 $\iff x \in A \setminus B \text{ and } x \in A \setminus C$
 $\iff x \in (A \setminus B) \cap (A \setminus C)$
 $\therefore A \setminus (B \cup C) \subseteq (A \setminus B) \cap (A \setminus C)$

Doing this for the other direction:

$$A \setminus (B \cup C) = (A \setminus B) \cap (A \setminus C)$$
Let $x \in (A \setminus B) \cap (A \setminus C)$
 $\iff x \in A \setminus B \text{ and } x \in A \setminus C$
 $\iff x \in A \text{ and } x \notin B \text{ and } x \in A \text{ and } x \notin C$
 $\iff x \in A \text{ and } x \notin B \cup C$
 $\iff x \in A \setminus (B \cup C)$
 $\therefore (A \setminus B) \cap (A \setminus C) \subseteq A \setminus (B \cup C)$

1.8 Von Neumann Ordinals

The von Neumann ordinals are a way of representing the natural numbers using sets.

let
$$0 = \emptyset$$
, $n + 1 = n \cup \{n\}$:

$$\begin{split} 0 &= \emptyset \\ 1 &= \{0\} = \{\emptyset\} \\ 2 &= \{0,1\} = \{\emptyset,\{\emptyset\}\} \\ 3 &= \{0,1,2\} = \{\emptyset,\{\emptyset\},\{\emptyset,\{\emptyset\}\}\} \} \\ n &= \{0,1,2,...,n-1\} \text{ you get the idea} \end{split}$$

2 Relations

2.1 Cartesian product and relations

The cartesian product of two sets A and B is the set of all ordered pairs (x, y), where: $x \in A$ and $y \in B$. The cartesian product of A and B is denoted as $A \times B$.

Example:

```
Books = \{1984, Concrete, Incerto\}
Rating = \{Good, Evil, Unimportant\}
Books \times Rating = \{(1984, Good), (1984, Evil), (1984, Unimportant)\}
\cup \{(Concrete, Good), (Concrete, Evil), (Concrete, Unimportant)\}
\cup \{(Incerto, Good), (Incerto, Evil), (Incerto, Unimportant)\}
```

A relation R from A to B is a subset of the cartesian product of A and B. i.e. $R \subseteq A \times B$. Taking the example above, we can define a relation R from Books to Rating as:

```
R = \{(1984, Good), (Concrete, Evil), (Incerto, Unimportant)\}
```

Note that R is a subset of the cartesian product of Books and Rating.

2.2 Relation notation

There are three main ways to denote a relation R from A to B:

- Ordered pairs
- Table
- Mapping

Should you want to confuse yourself even further, the infix notation is a good option.

```
Let the relation "likes" be defined as: \mathbf{L} = \{(x, y) | x \text{ likes } y\}
You can denote (x, y) as a subset of the likes by writing: \mathbf{x}\mathbf{L}\mathbf{y}
```

2.3 Representing relations

Since winter is approaching, let's define a relation "likes" from people to clothing.

```
Let the set of people P = \{\text{Jim}, \text{Bob}, \text{Alice}, \text{Eve}, \text{Mallory}\}
Let the set of clothing C = \{\text{Jacket}, \text{Scarf}, \text{Gloves}, \text{Hat}, \text{Socks}\}
Let the relation \mathbf{L} = \{(x,y)|x \text{ likes }y\}
In table form:
```

| Р | L |
|----------------------|--------|
| Jim | Scarf |
| Bob | Jacket |
| Alice | Scarf |
| Eve | Gloves |
| Mallory | Hat |
| Mallory | Socks |

Since a table popped into your view, it is as good a time as any to introduce it's application in databases.

Given this example relation of students and their various attributes, we can represent it in a table.

Let the set of students $S = \{Jim, Bob, Alice, Eve, Mallory\}$

Let the set of attributes $A = \{ \text{name}, \text{Age}, \text{Height}, \text{Weight}, \text{textHappiness}, \text{Net Worth} \}$

Let the relation $\mathbf{R} = \{(x, y) | x \text{ has attribute } y\}$

In table form:

| Name | Age | Height | Weight | Happiness | Net Worth |
|---------|-----|--------|--------|-----------|-----------|
| Jim | 20 | 180 | 80 | 0.5 | 0.1 |
| Bob | 21 | 170 | 70 | 0.6 | 0.2 |
| Alice | 19 | 160 | 60 | 0.7 | 0.3 |
| Eve | 18 | 150 | 50 | 0.8 | 0.4 |
| Mallory | 17 | 140 | 40 | 0.9 | 0.5 |

We can extract information by getting a subset of relations.

For example: $(Jim, 180) \in Height$

2.4 Domain and range

The domain of a relation is the set of all first elements of the ordered pairs in the relation.

$$Dom(\mathbf{L}) = \{ x \in A \mid \exists x \in A : (x, y) \in \mathbf{L} \}$$

The range of a relation is the set of all second elements of the ordered pairs in the relation.

$$Ran(\mathbf{L}) = \{ y \in B \mid \exists y \in B : (x, y) \in \mathbf{L} \}$$

2.5 Relational composition

The relational composition of two relations \mathbf{R} and \mathbf{S} is the relation $\mathbf{R} \circ \mathbf{S}$ (or $\mathbf{R}; \mathbf{S}$, used to avoid confusion with function composition) defined as:

$$\begin{aligned} \mathbf{R}; \mathbf{S} &= \{(x,z) \mid \exists y \in B : (x,y) \in \mathbf{R} \text{ and } (y,z) \in \mathbf{S} \} \\ \text{EXAMPLE:} \\ \mathbf{R} &= \{(1,2), (2,3), (3,4) \} \\ \mathbf{S} &= \{(2,3), (3,4), (4,5) \} \\ \mathbf{R}; \mathbf{S} &= \{(1,3), (2,4), (3,5) \} \end{aligned}$$

2.6 Closures and equivalence classes

2.6.1 Property of relations

A relation **R** is reflexive if $\forall x \in A : (x, x) \in \mathbf{R}$.

A relation **R** is symmetric if $\forall x,y \in A: (x,y) \in \mathbf{R} \implies (y,x) \in \mathbf{R}$. A relation **R** is transitive if $\forall x,y,z \in A: (x,y) \in \mathbf{R}$ and $(y,z) \in \mathbf{R} \implies (x,z) \in \mathbf{R}$.

2.6.2 Closures

The closure of a relation ${\bf R}$ is the smallest relation containing ${\bf R}$ that is transitive.

Example of constructing a reflexive closure:

Let the relation
$$\mathbf{R} = \{(1,2), (2,3), (3,4)\}$$

The reflexive closure of $\mathbf{R} = \{(1,1), (1,2), (2,3), (3,4), (2,2), (3,3), (4,4)\}$

Example of constructing a symmetric closure:

Let the relation
$$\mathbf{R} = \{(1,2), (2,3), (3,4)\}$$

The symmetric closure of $\mathbf{R} = \{(1,2), (2,3), (3,4), (2,1), (3,2), (4,3)\}$

Example of constructing a transitive closure:

Let the relation
$$\mathbf{R} = \{(1,2), (2,3), (3,4)\}$$

The transitive closure of $\mathbf{R} = \{(1,2), (2,3), (3,4), (1,3), (2,4), (1,4)\}$

2.6.3 Equivalence classes

let $\rho \subseteq A \times A$ be an equivalence relation on A, given $A \neq \emptyset$, $a \in A$ be an arbitrary element of A.

NOTE: MUST CONSTRUCT EQUIVALENCE RELATION BEFORE CONSTRUCTING EQUIVALENCE CLASSES.

$$[a]_{\rho} = \{ x \in A \mid (a, x) \in \rho \}$$

2.6.4 More properties of relations

- A relation **R** is antisymmetric if $\forall x, y \in A : (x, y) \in \mathbf{R}$ and $(y, x) \in \mathbf{R} \implies x = y$.
- A relation R is a partial order if it is reflexive, antisymmetric, and transitive.
- A connex relation is a relation **R** such that $\forall x, y \in A : (x, y) \in \mathbf{R}$ or $(y, x) \in \mathbf{R}$
- Total order means that a relation is a partial order and a connex relation.

3 Functions

3.1 Definition

What is a function in the context of discrete mathematics?

A function is a relation **f** from A to B such that every element in A is mapped to exactly one element in B, i.e.:

$$\forall x \in A. \forall y, z \in B : ((x, y) \in f \land (x, z) \in f \implies y = z).$$

3.2 Notation

A function **f** from A to B is denoted as $\mathbf{f}: A \to B$.

3.3 Injective, surjective, bijective

- A function $\mathbf{f}: A \to B$ is injective if $\forall x, y \in A: \mathbf{f}(x) = \mathbf{f}(y) \implies x = y$.
- A function $\mathbf{f}: A \to B$ is surjective if $\forall y \in B: \exists x \in A: \mathbf{f}(x) = y$.
- A function $\mathbf{f}: A \to B$ is bijective if it is both injective and surjective.

3.4 Composition

The composition of two functions $\mathbf{f}:A\to B$ and $\mathbf{g}:B\to C$ is the function $\mathbf{g}\circ\mathbf{f}:A\to C$ defined as:

$$\mathbf{g} \circ \mathbf{f} = \{(x, z) \mid \exists y \in B : (x, y) \in \mathbf{f} \text{ and } (y, z) \in \mathbf{g} \}$$

3.5 Inverse

The inverse of a function $\mathbf{f}: A \to B$ is the function $\mathbf{f}^{-1}: B \to A$ defined as:

$$\mathbf{f}^{-1} = \{ (y, x) \mid (x, y) \in \mathbf{f} \}$$

4 Language and regular expressions

4.1 Alphabet

We specify an Alphabet using the symbol Σ . Examples:

$$\begin{split} &\Sigma_1 = \{a,b,c,d,e,f\} \\ &\Sigma_2 = \{0,1,2,3,4,5,6,7,8,9\} \\ &\Sigma_3 = \{S \mid S \subseteq \Sigma_1\} \\ &\Sigma_4 = \{(x,y) \mid x \in \Sigma_1 \land y \in \Sigma_2\} \end{split} \qquad \text{(The power set of } \Sigma_1, \#\Sigma_3 = 2^6 = 64) \end{split}$$

An alphabet must be a set that contain finite elements, hence sets like $\mathbb{N} = \{1, 2, 3, 4, 5, 6, 7, 8, 9, \ldots\}$ cannot be the alphabet of a language.

4.2 Strings

A string is a finite sequence of characters from an alphabet.

A string of length n is denoted as the n-tuple $w=a_1a_2a_3...a_n$, written without punctuation.

The set of all finite strings are denoted as Σ^* , and we can say that string s is in Σ^* if $s \in \Sigma^*$.

4.2.1 Empty string

Might be jarring to you, Jim, but you have the option to denote an empty string as ϵ . Will be useful later on.

4.2.2 String Operations

- Concatenation: w_1w_2 is the concatenation of strings w_1 and w_2 .
- Length: |w| is the length of string w. The length of concatenated strings are simply the sum of the lengths of the individual strings.

4.3 Language

A language is a set of strings.

4.4 Regular expressions

A regular expression is a string that denotes a language. Here are the rules:

- $lwt\Sigma$ be an alphabet.
- a denotes the language $\{a\}$, where $a \in \Sigma$, which is on its own a regular expression.
- ϵ and \emptyset denote the languages $\{\epsilon\}$ and \emptyset , which are also regular expressions.
- Given r and s as regular expressions, the following are also regular expressions:

$$-rs, r|s, r^*$$

4.4.1 Examples

The following are rules for matching strings to RegEx, let s be a string and r be a regular expression:

- s matches a when s = a
- ϵ matches ϵ when $s = \epsilon$
- Ø matches nothing.
- r|s matches r or s.
- rs matches r followed by s.
- r^* matches if $s = \epsilon$ or $s = s_1 s_2 ... s_n$, where s_i matches r for all i.

4.4.2 Regular languages

A language is regular if it is denoted by a regular expression.

For alphabet Σ and regular expressions r:

$$L(r) = \{s \in \Sigma^* \mid s \text{ matches } r\}$$

5 Finite automata

5.1 Deterministic finite automata

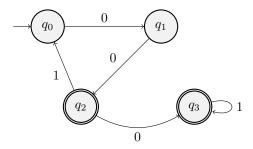

States: $Q = \{q_0, q_1, q_2, q_3\}$

Symbol: $\Sigma = \{0, 1\}$

Transition Function $\delta: Q \times \Sigma \to Q$

Start: $= q_0 \in Q$

Accepting: $= \{q_2, q_3\} \subseteq Q$

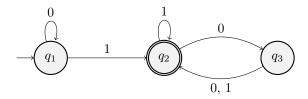

5.2 Non-deterministic finite automata

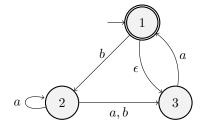

5.3 Examples

 $Referenced from \ \verb|https://www3.nd.edu/~kogge/courses/cse30151-fa17/Public/other/tikz_tutorial.pdf.$

5.3.1 DFA 1

5.3.2 NFA 1

5.3.3 DFA 2
